⑤ Electrical connector and connecting element.

⑦ A contact element formed in one piece comprises a pair of sinuous springs (28) extending from opposite ends of a side of a channel shaped central section (12) from the other side of which extensions (24) define a centrally supported beam spring (20) having ends (22) engageable with contact portions (38) at ends of the springs (28). In use a connector is formed by a slab-like block of insulating material formed with cells opening to opposite faces and each containing a contact element (10). The beam spring (20) of each element engages a cell wall to flex ends (22) against the contacts (38). Contacts (38) of the sinuous springs project outwardly of the block to engage contacts of substrates between which the connector is sandwiched.

EP 0 009 314 A1

Electrical Connector and connecting element

This invention relates to electrical connectors and to connecting elements for use in such connectors, and is particularly concerned with connectors of the kind used
5 for interconnecting electrical contacts on spaced substrates or printed circuit devices. Such connectors generally comprise a slab like body of insulating material containing a closely spaced, grid array of contacts extending between opposite faces of the body to present
10 contact points at the opposite faces where portions of the contacts are exposed.

Recent advances in micro-circuit technology have led to the requirement that connectors of this kind have contacts at very small spacing and that the contacts be
15 extremely small. Difficulty is present in providing such a connector in which the contacts can generate and maintain adequate contact force with acceptably low values for resistance, inductance and capacitance.

A contact element according to the present
20 invention is stamped and formed in one piece from sheet metal and has a central section of generally channel shape, one side of the channel having strip-like extensions bent to extend in sinuous spring form lengthwise and from opposite ends of the channel, free ends of
25 the sinuous spring portion defining contact portions, and the other side of the channel being extended at opposite ends to define a resilient spring beam extending at its free ends to respective contact portion.

The invention also includes a connector comprising
30 a slab-like insulating housing formed with a plurality of

cells opening between opposite faces of the housing, each cell containing a contact element according to the invention, contact portions of each contact element projecting from opposite sides of the housing and the resilient spring beam engaging a side of the cell to flex ends of the spring beam against respective contact portions of the element.

The invention will now be described, by way of example, with reference to the accompanying partly diagrammatic drawings, in which:-

Figure 1 is a side elevation of a connecting element according to the invention;

Figure 2 is a plan view of the element of Figure 1, and,

Figure 3 is a fragmentary perspective view, partly in section of a connector assembly according to the invention.

The connecting element 10 of Figures 1 and 2 is stamped and formed in one piece from sheet metal in strip form, and a suitable material is Beryllium copper. The element has a stable centre section 12 from which strip-like sinuous portions 28 extend on opposite sides in symmetrical manner in the sense that the upper portion 28 is the mirror image of the lower portion 28. A strap portion 14 extends perpendicularly from a rear side, as seen in Figure 1, and upper side as seen in Figure 2 of the centre section 12, beyond the width of the section 28, and is then bent perpendicularly at 18 to extend in spaced parallel relation with respect to the centre section 12. A dimple 16 is formed centrally of the strap portion to project outwardly of the element, i.e. upwardly as seen in Figure 2.

The bent portion of the strap 14 is extended upwardly and downwardly as seen in Figure 1 to define a strip-like spring beam 20 of width, as seen in Figure 2,

substantially equal to the width of the strip-like sinuous portion 28, but of lesser length, as seen in Figure 1, terminating at its ends 22, short of upper and lower extremities of the sinuous portions 28. The beam 20 is centrally supported at the strap portion 14 and has upper and lower spring sections 24, each of which extends initially in straight, coplanar relation away from the central support and is then convexly curved at 26, in a sense facing away from the respective sinuous portions 28, with the free end 22 lying substantially in the plane of the centrally supported portion.

The sinuous portions 28 each comprise double-S shaped sections terminating in contact portions 30 at the free end bent back in generally square box-like fashion, as seen in Figure 1, to define three contact sides, 32, 34 and 36, with the free end of the sinuous portion being disposed on a side of the box remote from the associated spring section 24, and turned inwardly in arcuate fashion. Each of the sides 32, 34 and 36 is provided generally centrally with a dimple 38 projecting outwardly of the box-like form and that on the side 32 facing the end 22 of the associated spring arm 24 from which it is spaced by a small distance.

The assembly of Figure 3 comprises a flat slab-like housing 40 of insulating material formed with rows of cells 42, each cell being of generally rectangular section and extending perpendicularly between opposite faces of the housing between open ends. A wall of each cell is formed with an aperture 50 of generally oval form, elongate longitudinally of the cell and adapted to register with the strap dimple 16 of a contact element in the cell 42. Each cell is adapted to receive a contact element 10 and is so dimensioned relative to the contact element 10 that the beam 20 is deflected to engage its free ends 22 with the contact dimples 32, with the peak 26

of the convex spring portions abutting the cell wall on one side, and on the opposite side the dimples 38 being urged against the opposite cell wall. The strap dimple 16 engages in the cell wall aperture 50 to allow for limited relative movement of the contact element 10 in the cell 42. The contact sections 30 project externally of the housing 40 to expose the contact dimples 38 at opposite sides.

Adjacent rows of cells 42 are staggered so that contact dimples 38 of alternate rows are offset from those of intermediate rows by half the cell spacing in a row. This arrangement is adapted for the interconnection of circuit pads 44 arranged in similar staggered array on upper and lower circuit laminae 48 and 46. In use the connector is sandwiched between the laminae with contact pads 44 in registration with respective contact dimples 38. The sinuous spring portions 28 are flexed by compression between the laminae to generate contact pressure, and the contact dimples 38 are worked against the spring end portions 22 by relative sliding.

The spring 20 serves to provide a shorter electrical path than that of the sinuous spring portions 28 whereas the portions 28 define compliant spring portions adapted to deal with board irregularities without risk of overstress. Flexure of the spring 20 resists relaxation of the contact 22.38.

Claims:-

1. A contact element stamped and formed in one piece from sheet metal characterised by a central section 12, 14 of generally channel shape, one side of the channel having strip-like extensions 28 bent to extend in sinuous spring form lengthwise and from opposite ends of the channel, free ends of the sinuous spring portions defining contact portions 30, and the other side of the channel 12, 14 being extended at opposite ends to define a resilient spring beam 20 extending at its free ends 22 to respective contact portions 30.
2. A contact element as claimed in claim 1., characterised in that the free end 30 of each sinuous spring portion 28 is folded in generally square box-like form to define three sides 32, 34, 36.
3. A contact element as claimed in claim 2., characterised in that each of the three sides 32, 34, 36 of the box-like contact portion 30 is formed with an outwardly projecting dimple 38, and the dimple 38 on the side adjacent the spring beam 20 is arranged to engage an end 22 of the beam 20 on flexure of the spring beam 20.
4. A contact element as claimed in claim 1., characterised in that portions 26 of the spring beam 20 on opposite sides of the central section 12, 14 are curved convexly away from the adjacent sinuous spring portion 28.
5. A contact as claimed in claim 1., characterised in that each of the sinuous spring portions 28 is formed as a double-S-shaped spring.
6. An electrical connector comprising a slab-like insulating housing formed with a plurality of cells opening at opposite sides of the housing, characterised by each cell containing a contact element as claimed in claim 1., contact portions 30, 38 of the element 10 projecting from opposite sides of the housing 40, and the resilient spring beam 20 engaging a side of the cell 42 to

flex ends 22 of the spring beam 20 against respective contact portions 30 of the element 10.

7. A connector as claimed in claim 6.,
characterised in that portions 26 of the spring beam 20
5 of each contact element 10 on opposite sides of the central
section 12, 14 are curved convexly away from the adjacent
sinuous spring portion 28.
